

Availability Calculation Overview

Purpose:

- Optional step before launching orders in preparation.
- Determines whether selected orders can be fully served based on current stock availability.
- Helps identify if restocking a preparation area is necessary before picking.

Access:

- Configured in SpeedWMS for selected orders prior to launch.
-

Types of Availability Rates

1. Absolute Rate

- Calculated for the entire warehouse.
- Provides an overall availability of items.
- Considers the total need of the orders.

2. Proximity Rate

- Calculated for an advanced preparation zone.
- Determines if goods transfers to this zone are required.
- Total need is taken into account.

3. Retail Rate

- Calculated for areas where retail withdrawals occur.
 - Only considers the requirement outside full pallets.
 - Useful for small-quantity or picking operations.
-

Key Notes

- Not all three rates need to be configured; only the required rate can be set.
- Provides a pre-launch check to optimize stock allocation and reduce preparation delays.
- The calculated rates can influence launch decisions, especially if stock is insufficient.
