

Topic: Replenishment Generation

Access Path: Preparation / Replenish. → Click the 'Generate' button (located on the right side of the interface).

Purpose: This function launches a process to calculate and create replenishment tasks based on user-defined criteria.

1. Generation Window & Criteria

The Replenishment Generation Window is the interface where users define the criteria for the system to calculate required replenishments.

- **Primary Selection:** You must first select the picking area (zone) concerned by the generation.
- **Granular Selection:** Within the selected zone, you can further narrow the scope by specifying:
 - A single Item
 - A single Location
 - An Item Family
- **Parameter Initialization:** When a zone is selected, all other calculation parameters (e.g., min/max levels) are automatically initialized with the values defined for that zone.

2. Key Parameter: "Complete Pickings"

- **Purpose:** When enabled, this parameter directs the system to generate replenishments with the sole goal of filling existing picking tasks, regardless of the standard stock level requirements.
- **Effect:** It ensures that all items requested in open pickings are fully available at the picking location.

3. Execution

- **Process:** After defining the criteria, click the dedicated validation/confirmation button in the window.
- **Outcome:** This action triggers the system's calculation engine, which processes the inputs and generates the specific replenishment tasks desired by the user.
